University of Belgrade, Faculty of Sport and Physical Education

Homework — week 2

Statistics in Physical Education and Sport · chapters 6 and 7 · submit in Teams before the next class (Friday, 20 Nov 2026, 8:00)

Problems 1–9 come from the textbook instructor guide (Weir & Vincent, 2021, "Problems to Solve"); 10 and 11 were added for parts 3 and 4 of the lecture. Do not use the tables in the textbook appendix. Compute probabilities, percentages and quantiles in jamovi with the distrACTION module: install it once (+ Modules → jamovi library), then distrACTION → Normal Distribution (Mean = 0, SD = 1; Probability, P(X ≤ x1) or P(x1 ≤ X ≤ x2)) and T-Distribution (Quantile(s)). Compute the rest by hand or in jamovi. Show your work for every answer. Submit one document in Teams. Grade: 0–10 points; late submissions are not accepted.

Chapter 6 — the normal curve

1. What percentage of the values in a population lies between the mean and z = +0.35?
2. A data set has a mean of 25.7 and a standard deviation of 5.2. Compute the z scores of the raw scores (a) 21.6, (b) 28.9 and (c) 24.5. How do you interpret these z scores?
3. Find the percentile rank of each score in problem 2.
4. Convert the z scores from problem 2 to T scores.
5. What is the stanine of each score in problem 2? (Stanine limits in z: ±0.25, ±0.75, ±1.25, ±1.75; textbook, fig. 6.6.)
6. Compute the odds for the probabilities (a) .50, (b) .25, (c) .10, (d) .05 and (e) .01.

Chapter 7 — fundamentals of statistical inference

7. Compute the standard error of the mean for the three samples in the table. What can you say about the standard error in relation to the standard deviation and N?

Sample	SD	N
A	21.4	36
B	2.1	106
C	56.7	19

8. You want to estimate the mean maximal oxygen uptake ($\dot{V}O_2max$, ml/kg/min) of all female students at a university. You randomly select 50 names from the registrar's list and invite them to be tested; 35 accept. The sample mean is 38.5 and the standard deviation 4.7. What is the 95% confidence interval for the population mean? Compute it with t (df = 34) as well and compare. Is this still a random sample? Explain in two sentences.
9. The file STAT_DAS_N02_Homework_Jumps.xlsx holds the sample of 50 standing long jumps from the lecture (part 2), drawn from a population of 15,000 schoolchildren. In jamovi, compute N, minimum, maximum, mean, standard deviation, standard error and the 95% confidence interval. Do the numbers make sense? The population mean is 174.87 cm: does the interval contain it, and what would it mean if it did not?
10. Data from problem 8: a researcher wants to test whether the population mean differs from 40 ml/kg/min. Write the null and the (nondirectional) alternate hypothesis, compute z and the p value, and decide with α = .05. Does the interval from problem 8 lead to the same decision? Which type of error might you have made?

11. Only after computing, the same researcher says: “I expected the mean to be below 40” and uses a one-tailed test. What is the p value then, and what is the decision? Why is this not correct, and when would a one-tailed test be justified?
